It describes how bone and cartilage develop in embryos and are maintained in adults, how bone is repaired when we break a leg, or regenerates when a newt grows a new limb, or a lizard a new tail.

Growth and Development of Bones Early in the development of a human fetus, the skeleton is made entirely of cartilage. The relatively soft cartilage gradually turns into hard bone through ossification. This is a process in which mineral deposits replace cartilage.

13.12: Growth and Development of Bones - Biology LibreTexts

Throughout fetal development and into childhood growth and development, bone forms on the cartilaginous matrix. By the time a fetus is born, most of the cartilage has been replaced with bone. Some additional cartilage will be replaced throughout childhood, and some cartilage remains in the adult skeleton. Intramembranous Ossification

Bone Formation and Development · Anatomy and Physiology

Bone and cartilage are two specialized forms of connective tissues which are composed of cells embedded within an extracellular matrix. Both bone and cartilage play an important role in protecting the internal organs of our body, providing structural support and surfaces for muscle attachment.

Difference between Bone and Cartilage -Bone vs Cartilage

Endochondral ossification occurs in long bones and most other bones in the body; it involves the development of bone from cartilage. This process includes the development of a cartilage model, its growth and development, development of the primary and secondary ossification centers, and the formation of articular cartilage and the epiphyseal plates.

Bone - Wikipedia

Compare and contrast the interstitial and appositional growth. In the early stages of embryonic development, the embryo's skeleton consists of fibrous membranes and hyaline cartilage. By the sixth or seventh week of embryonic life, the actual process of bone development, ossification (osteogenesis), begins.

6.4 Bone Formation and Development - Anatomy & Physiology

Tissues that are intermediate between cartilage bone (chondroid, chondroid bone) or intermediate between dentine and enamel (cementum, enameloid) are discussed from evolutionary and developmental perspectives. The concept of scleroblasts as basic skeletal-forming cells is reviewed, as are the cellular concepts of modulation and metaplasia.
