Duct systems are designed to properly distribute air throughout a building. Ducts that are not well designed result in discomfort, high energy costs, bad air quality, and increased noise levels. Choosing the right-sized duct is critical to maintain proper air flow in the system. Below is a simple model for determining duct sizes.

A round duct with a cross sectional area of 0.6m<sup>2</sup> has a perimeter of 2.75m. A rectangular duct with an equal cross sectional area has a perimeter of 3.87m. The rectangular duct therefore requires more metal for its construction, this adds more weight and costs to the design.

The design of exhaust duct systems is also straightforward. However, these systems are often process oriented and may require customizing to suit individual applications. The basic design process for exhaust or negative pressure systems is similar to that for supply or positive pressure systems.

A primary issue is the tradeoff between the initial cost of the duct system and the energy cost of the air distribution system. Larger ducts require a larger initial investment, but result in lower fan energy costs over the life of the system. Other issues include space restrictions, noise level, capacity for expansion, appearance,etc.

DUCTWORK DESIGN MISTAKE #2: Runs that are too long. When the location of HVAC equipment and duct system and not optimized in the planning phase, the equipment may end up far away from the space to be cooled. That may require long runs of ductwork that make it hard for your HVAC system to move conditioned air to certain areas within the space.
