The Arduino can input and output analog signals as well as digital signals. An analog signal is one that can take on any number of values, unlike a digital signal which has only two values: HIGH and LOW. To measure the value of analog signals, the Arduino has a built-in analog-to-digital converter (ADC).

Interrupts can come from various sources. In this case, we are using a hardware interrupt that is triggered by a state change on one of the digital pins. Most Arduino designs have two hardware interrupts (referred to as "interrupt0" and "interrupt1") hard-wired to digital I/O pins 2 and 3, respectively.

Resistors lower the voltage passing through them, and so to read changes in light from this circuit, you can use the Arduino's analog to digital converters (ADCs) to measure the voltage level of the input. The ADCs convert the analog value to an integer in the range 0 through 1023.
